Course Completed by

Jeff Mathew Sam

on: June 30, 2026

Overview

This course equips learners with essential knowledge of AI system security. They explore how vulnerabilities can be introduced during system architecture design, model development, training, prompt handling, and deployment, and examine threats such as prompt injection, adversarial examples, data poisoning, model extraction, and jailbreaks. Learners analyze real-world breaches and misuse cases—including deepfakes and model leaks—to understand emerging risks, misapplications, and the limitations of current defenses. Alongside these threats, they develop strategies for defenses, such as secure architectures, verifiable training, and prompt-level protections, gaining practical insight into how to assess and improve AI system security. By the end of the course, learners will be able to evaluate AI vulnerabilities, interpret security implications, and design more secure, robust, and trustworthy AI applications.

Competency Areas

Foundations of AI and Cybersecurity

AI System Architectures and Security Risks

Adversarial Inputs and Prompt Injection

Model Extraction and Data Poisoning

Misapplications, Misuse, and Real-World Breaches

Trustworthy and Secure AI System Design

Emerging Defenses and Verification Techniques

Credential / Credit Earned

Record of Completion in AI Security verified by the Stanford Engineering Center for Global & Online Education.

Grade: Satisfactory CEU-equivalent: 1
